

$N = 720$ (by the end of 2 months.)

$n = 70$ (the number of people who are still active after some time).

Slurps data.
Current numbers

P is one set of all the possible people pairs that we can make, here I can do off to two pairs. to use N or n . that leads to more 299

What is the fresh rate of a new observation.

So maybe I create an Variable.

I which is slightly more obvious on.

n . ~~called~~ about 0.6 of n that is 42.

$$I = \frac{6}{10} \times 720 = \underline{\underline{432 \text{ ppl.}}}$$

So I define P (Set of pairs from the people who will fresh this quiz are.)

$$I C_2 = 432 C_2$$

Or maybe we switch from the dyadic ways and use SC where Δ denotes the group size.

~~u~~ { football, music, anime, ... }.

and maybe we define a cutoff that
below this point the similarities are
real just. — how does one put it? No.
So for that I have τ ^{→ Cutoff (See at 11:30)}

Let's make a set of Set of features that
we will decide whether to ML-learn or
Hand tune. later. Let call it F .

And then we should be able to somehow
score this let's call that score for a
pair $S(u, v)$.

Let's say 432 ppl completed onboardg. ^{→ ~~started~~ played my game}

③
⑥
Then well after a suggestion from the game
we get maybe. when ppl send as suggestions.
from the game. now, $43 \times 5 = 2160$.

2160 . and they accept a suggestion. lets say. 0.3
 $0.3 - 0.4$, lets take 0.4 , 0.4×2160
 $= 864$ - Suggestion. Out of which say.

half reach a genuine comm. then, 432 imm.
then a study says. of which 0.15% will have
a durable friendship (might lead to creating or
fmg groups as well). So well. 1.5×43.2 .

$= 64.8$ → if groups are not fmed.

have minimum formation of friendships.

And well lets say ~~half~~ of them actually.

Respond to them
to their suggestion.

~~So~~
half
say yes and no.
 32.4

So we had 2160 ^{Suggestive} ~~Impressions~~ sent and will likely

receive a 32.4 feedback ~~or~~ outcomes that is
nonexistent to validate the data for GRL or.
Even ReL.

Guesstimate signed.

We can write elasticity estimates for these.
Maybe...

→ Don't use low
classifiers of
92.8.

$$\ln(x_i) = \ln(\$1) + \ln(n_1) + \ln(m_2) +$$

that means a n improvement of 10% more.
An improvement of 10% on any org will
lead to an imp of 10% or better.

Notice!

Simple Computation

What about the NLP based computation?

(Can we afford to do that every day?)

When that's well $\delta C_2 = .432 C_2$ (5)

lets say worst case. a 1000 diff.
interest rate

$$= 93096$$

1000^2
(non) $\times$ if then of
the Mon LL.
does?

Maybe 384

384 mlders.

Purely Computable.

So well the on just compute right.

Now maybe lets finally go ahead. and.
figure out the Education aspect.

So well. the paper guide us with.

IDF :- $df(a) = \text{document frequency}$

(7)

pdf = or inverse cannot have ss = weight eye for
 rec-~~the~~

$$\text{pdf}(a) = \ln \left(\frac{S+1}{d(a)+1} \right)$$

hmm... Now lets go and check for errors.

each of L has.

using a as an input. proving Θ of.
Binary (n, π) . pdf

$$\sigma = \sqrt{S \cdot P \cdot (1-P)}$$

from $\mathbb{Z}$ to $\mathbb{Z}$
 our approximation

~~So instead of~~
 lack of answer.

$$\lim_{S \rightarrow P} (\rightarrow) \geq 1$$

(2)

Well if $df=1$ then certainly very
cruc.

So we should try some similarity
instead. (That's why I did $a \cdot T$).

$$df \cdot a \quad (\leq V : \exists \text{ Som}(a_i) \geq T)$$

Asymmetric Gauge (Max Som).

$$\sum_a^U \text{edf}(a) \geq T$$

$$\exists (A_i \rightarrow A_i) //$$

Then maybe behavior non.

Consider differences
(Hall's conjecture)

Go

used. $S=O(1)$ say //

(9)

Now we're going to do the features. But before
that something else that is widely studied
comes to mind. Pairs or friends of maps.
And we've left a new course (Δ).

Need to find Δ in the degrees //

1. A Chaitin Overlap. (Cry in classes).
2. Colocation
3. Inset Overlap.
4. Schedule Overlap.
5. Region/degree
6. Room Assignment (Psychology)

Weights & Aspire:—

1. 0.25
2. 0.25
3. 0.25
4. 0.10
5. 0.05. (don't use cause region based clusters on degree)
6. (0.1)

The problem:— Some people who pick popular others will get more nodes
And others will be none. → Does not help the shy guy ☹️

So why don't we cap it
Every user will recommend 10.
[1, 10] peers

Then we have to study this.

More (~~often~~ S_{mean})

$$F(s) = (1 - \lambda) (K_{\text{omp}}) + \lambda (S_{\text{sig}})$$

$\hookrightarrow$ Taken from Mentares (1978)

Also this also requires 20% of the pop.
from mid tier matches. Some
well we do not have proper feedback
Numbers.
~~from this~~

R ND $\rightarrow$. Curves.
Reorganize

$$w = -\ln(p).$$

we will need 42-gms Co for.

CV- $\frac{1}{\sqrt{m}} //$

Schors $\rightarrow$ or briefing
H/All even.
